## DEPARTMENT OF WATER RESOURCES

P. BOX 388  
SACRAMENTO

March 15, 1965

Honorable Edmund G. Brown, Governor,  
and Members of the Legislature of  
the State of California

Gentlemen:

Bulletin No. 130-63, entitled "Hydrologic Data, Volume IV, San Joaquin Valley", presents data on hydrologic conditions in the San Joaquin Valley during the 1963 reporting year.

This bulletin is the first of a series which incorporates data on surface water, ground water, and climate previously published annually in Bulletins No. 23, 39, 65, 66, and 77. With the inauguration of the new series, publication of the earlier reports is discontinued.

Bulletin No. 130 will be published annually in five volumes, each volume to report hydrologic data for one of five specific reporting areas of the State. The area orientation map on page iii delineates these areas. Page ii outlines the organization of the bulletin, its volumes, and appendices.

The collection and publication of data as contained in Bulletin No. 130 are authorized by Sections 225, 226, 229, 230, 232, 345, 12609, and 12616 of the California Water Code.

The basic data programs of the Department of Water Resources have been designed to supplement the activities of other agencies to satisfy specific needs of the State. Bulletin No. 130 presents to the public useful, comprehensive, accurate, timely hydrologic data, which are prerequisites for effective planning, design, construction, and operation of water facilities.

Collection of much of the data presented has been possible only because of the generous cooperation and assistance of other agencies and many individuals; these cooperators are shown in the tables where appropriate. Without this assistance Bulletin 130-63 would be a much less valuable tool.

Sincerely yours,

A handwritten signature in dark ink, appearing to read "William E. Warne".

Reviewed and Coordinated by Division of Resources Planning Data Coordination Section

This is Volume IV in a series of basic data reports presented under a new format entitled "Bulletin 130-63, Hydrologic Data." The five volumes of the bulletin embrace the entire State of California, each volume being prepared by the area branch or district of the department responsible for the publication of basic data collected in its respective area. These areas are shown on the frontispiece map.

This report contains a record of hydrologic data collected and assembled by the San Joaquin Valley Branch of the Department of Water Resources. It brings together in a permanent and usable form the following types of hydrologic basic data collected during the respective time intervals as shown below:

Surface Water Flows	October 1, 1962 - September 30, 1963
Diversion Data	October 1, 1962 - September 30, 1963
Climate Data	July 1, 1962 - June 30, 1963
Ground Water Level Measurements	July 1, 1962 - June 30, 1963
Surface Water Quality	October 1, 1962 - September 30, 1963
Ground Water Quality	October 1, 1962 - September 30, 1963

#### Location and General Features of the San Joaquin Valley

The San Joaquin Valley includes approximately the southern two-thirds of the Great Central Valley of California. It is a broad structural trough surrounded on three sides by mountains: the Sierra Nevada on the east, the Coast Range on the west, and the Tehachapi and San Emigdio Mountains on the south. It is separated from the Sacramento Valley on the north by the combined deltas of the Sacramento and San Joaquin Rivers. The valley extends 250 miles southeasterly from Stockton to Grapevine at the foot of the Tehachapi Mountains; the width of the valley floor ranges from 25 miles near Bakersfield to 55 miles near Visalia and averages about 35 miles. The area of the valley floor is 10,000 square miles, excluding the rolling foothills that skirt the mountains.

East of the San Joaquin Valley the Sierra Nevada rises in a distance of 45 to 60 miles to altitudes of 14,000 feet or more; to the west the Coast Range rises to 6,000 feet; and on the south the valley is enclosed by the San Emigdio and Tehachapi Mountains which rise to altitudes of about 8,000 feet. Only at Carquinez Strait, a break in the Coast Range east of San Francisco Bay, does the Great Central Valley open to the sea.

The valley floor rises gently from sea level at the north end to 500 feet above sea level about 21 miles south of Bakersfield; alluvial fans along the valley borders rise to altitudes as high as 700 to 1,800 feet. The gentle northward gradient of the valley floor is interrupted by a low divide in the neighborhood of the Kings River, about 15 miles west of Hanford; the San Joaquin Valley is divided at that point into two separate drainage basins - the San Joaquin River Basin and the Tulare Basin.

#### Scope of Report

The areal scope of this volume of the report is depicted on Plates A-1, B-1, C-1, D-1, and E-1. The location of climatological stations for which data are presented is shown on Plate A-1 and the location of surface water gaging stations on Plate B-1. The basins, subbasins, or areas in the San Joaquin Valley for which ground water levels are reported are shown on Plate C-1. The locations of surface water sampling stations are shown on Plate D-1, and the basins, subbasins, or areas used to locate the ground water quality samples are shown on Plate E-1.

The following chapters present information on precipitation, evaporation, and temperature, surface runoff, diversions, reservoir storage, imported water supplies, ground water conditions, and quality of surface and ground water.

The tabulated basic data are presented in Appendixes A through E. These appendixes include all basic data collected pertaining to climate, surface water flow, ground water level measurements and water quality analyses of surface and ground water.

#### Numbering System Designations

In the paragraphs which follow, there are presented descriptions of the various numbering and coding systems used in this report. These systems are utilized to facilitate machine data processing.

#### Region Designation

The region designations used in this report pertain to geographic areas as defined in Section 13040 of the Water Code. The State is divided into nine regions and the San Joaquin Valley area encompasses that portion of the Central Valley region south of the north boundary of the Stanislaus River drainage area.

#### Climate Station Designation

The climatological station designations used herein and in Appendix A are based on the drainage basin and alpha number. Stations are also named and latitude and longitude locations are determined to the nearest minute.

Each main drainage basin is assigned a letter and each subbasin a number, as shown on Plate A-1 of this report.

The alpha order number is assigned each station to denote its order in alphabetical sequence for machine processing. The subnumbers are used to avoid duplication of the original four-digit system for machine processing. Only 21 columns are available for station name; therefore, some abbreviations are necessary.

#### Surface Water Gaging Station Designation

The index number for each gaging station is composed of a number which begins with an alphabetical letter designating the hydrographic area, followed by the first digit which indicates the main river basin. The second digit refers to a tributary of the main river basin. The hydrographic area and the river basins are outlined on Plate B-1. The remaining three digits are used to number stations in an upstream direction with the lowest number at or near the mouth. The digit 9, which is the third from the left, indicates that the station is a surface gravity diversion station. Each station is listed by name as well as by machine index number.

#### Ground Water Basin and Area Designation

With respect to the basin numbering system code, a decimal numbering system of the form 0-00.00 has been used. The number to the left of the dash refers to the geographic region described above. On the right of the dash, the first two digits refer to a hydrographic unit, generally designated as a basin, valley, or area. These are followed by decimals which designate a subbasin, area, or subarea within the basin. These basins, areas, or subareas are shown on Plates C-1 and C-2.

### Well-numbering System

The state well-numbering system used in this report is based on township, range, and section subdivision of the Public Land Survey. It is the system used in all ground water investigations and for numbering all wells for which data are published or filed by the Department of Water Resources. In this report, the number of a well assigned in accordance with this system is referred to as the state well number.

Under this system, each section is divided into 40-acre tracts lettered as follows:

D	C	B	A
E	F	G	H
M	L	K	J
N	P	Q	R

Wells are numbered within each 40-acre tract according to the chronological sequence in which they have been assigned state well numbers. For example, a well which has the number 16S/15E-17K1 M would be in Township 16 South, Range 15 East, Section 17, M.D.B.&M., and would be further designated as the first well assigned a state well number in Tract K. In this volume, well numbers are referenced to the Mount Diablo Base and Meridian (M), or the San Bernardino Base and Meridian (S).

## CHAPTER II

### CLIMATE

#### Introduction

The climate of the San Joaquin Valley is characterized by hot summers and mild winters. Midday temperatures in midsummer are high, occasionally 110° F. with extremes as high as 120° F. having been recorded. The diurnal temperature variation also is extreme, especially in summer when frequently it is 40° F. or more.

Annual precipitation decreases from north to south and east to west across the valley. The average annual precipitation ranges from 5.38 inches at Buttonwillow in the southern part of the valley to 17.42 inches at Knights Ferry in Stanislaus County at the northern end of the valley. Precipitation figures are based on the 50-year mean period 1910-1960.

As moist air moves in from the Pacific Ocean and ascends the western slope of the Sierra Nevada, precipitation increases and reaches a maximum in the higher parts of the range. The mean annual precipitation exceeds 40 inches in much of the higher mountainous part of the Sierra Nevada tributary to the San Joaquin Valley and exceeds 60 inches in small isolated areas. During winter, snowfall is heavy in the Sierra Nevada at elevations above 3,000 to 4,000 feet.

Precipitation and runoff in the Central Valley vary not only from winter to summer, but from year to year.

#### Scope

The area covered by this report and its geographical relation to the Central Valley Drainage Basin are both shown on Plate A-1.

The Department of Water Resources gathers basic data relating to climatic phenomena in the San Joaquin Valley. This involves field measurements and office computations to determine the instantaneous, daily, monthly, seasonal, and annual temperatures, precipitation, and evaporation.

The field activities include the installation and maintenance of weather stations. The installed equipment obtains measurements of: (1) daily maximum and minimum temperatures; (2) precipitation - annual amounts from storage gages in remote areas, daily amounts from standard rain gages, and instantaneous amounts from recording rain gages; (3) evaporation in inches per day; and (4) wind movement in miles per day. In addition, similar data are obtained from many public and private agencies and individuals.

The department contributes to the cooperative program with the U. S. Weather Bureau by providing services for the installation, maintenance, and operation of approximately 100 stations in the State, eight of which are located in the San Joaquin Valley. The U. S. Weather Bureau publishes these data in the official U. S. Weather Bureau publication, "Climatological Data."

The office activities consist of computation and compilation of approximately 150 monthly climatological station observations to provide a continuous and current record. This includes the computation of intensities from recording rain gages and preparation of hourly precipitation records for future use in development of rainfall intensity-duration-frequency relationships.

#### Precipitation

Precipitation during the 1962-63 season for the San Joaquin Valley area as a whole was normal. This is a continuation of two years of normal rainfall in the valley preceded by three years of below-normal precipitation.

This year's precipitation, measured from July 1, 1962, through June 30, 1963, varied from 109 percent of normal at Modesto on the north to 74 percent at Bakersfield on the south. The greatest deviations from normal were 131 percent at Mariposa and 65 percent at Maricopa.

The San Joaquin Valley area may be divided into three general parts: the west side, the valley floor, and the east side or Sierra Nevada. Table 1, "Seasonal and Mean Precipitation at Selected Stations in the San Joaquin Valley," shows the distribution of rainfall west to east across the valley. Averages of precipitation normals show for the west side stations 6.3 inches, for the valley floor 9.7 inches, and for the east side 16.6 inches.

The seasonal deviation from normal of the three general areas is 86 percent on the west side, 103 percent on the valley floor, and 109 percent on the east side.

TABLE 1  
SEASONAL AND MEAN PRECIPITATION AT  
SELECTED STATIONS IN THE SAN JOAQUIN VALLEY

C2 4890	Lemon Cove	Tulare	13.68	11.88	87
C0 7077	Porterville	Tulare	10.39	8.99	87

Three incidents of relative climatological importance occurred during the 1962-63 season: The storm of October 8 through October 15, 1962, raised the valley precipitation to 89 percent of normal after a dry fall; for the period January 30 through February 2, a high intensity storm struck the valley again, raising the averages to 71 percent of normal after the November and December doldrums of fog and cold; the gradual and general cool rains of April, followed by above-normal precipitation in May and June, resulted in normal to above normal precipitation for the year.

The occurrences described above are shown in Table 2 "Cumulative Monthly Precipitation at Key Stations in the San Joaquin Valley."

The San Joaquin Valley area normally receives 80 percent of the total seasonal precipitation by April 1. Also, by this date, maximum snowpack has been attained in the Sierras. On April 1, 1963, the valley floor had received rainfall in accumulated totals ranging from 92 percent of normal at Modesto on the north to 62 percent at Bakersfield on the south. Snowpack accumulation in the adjacent Sierras was only 35 percent of normal; however, the precipitation patterns of April, May, and June were far above normal: A new April high of 2.38 inches was established at Hanford superseding a long-term record of 2.67 inches recorded in 1926, and covering most of the Sierra watershed with excessive amounts. This resulted in normal to above normal precipitation, varying from 100 percent for the Tule River watershed to 130 percent for the Kings River watershed.

The distribution of rainfall on the entire area may be seen on Plate A-2, "Lines of Equal Precipitation, July 1, 1962, to June 30, 1963."

#### Temperatures, Evaporation, and Wind Movement

The distribution of temperatures, evaporation, and wind movement is presented in Table 3, "Average Temperatures, Total Evaporation and Average Wind Movement at Selected Stations in the San Joaquin Valley."

CHAPTER III  
SURFACE WATER FLOW

Introduction

The variable flows of the streams entering the San Joaquin Valley on the east side result from the rainfall runoff occurring each winter and spring season, principally from December through April. The snowmelt runoff occurs during the spring and summer months from March through June. A combination of runoff from perennial tributaries and released stored water occurs during the summer and fall seasons. Flood flows in the valley floor channels are caused by runoff from rainfall and melting snow in the mountain areas in excess of mountain reservoir capacities, and by rainstorm runoff from the vast area of minor foothill watersheds and valley floor lands. In more recent years, flooding has become a lesser threat in the San Joaquin Valley as a result of additional reservoirs constructed on many of the tributary watersheds, including the Kern, Tule, Kaweah, Kings, San Joaquin, Merced, Tuolumne, and Stanislaus Rivers. With the completion of the Lower San Joaquin River Flood Control Project and eventual construction of additional dams and reservoirs, such as Buchanan on the Chowchilla River, Hidden on the Fresno River, and New Melones on the Stanislaus River, flooding will cease to be a problem in the San Joaquin Valley except in years of excessive precipitation.

Scope

The area covered by this report and its geographical relation to the Central Valley Drainage Basin is shown on Plate B-1.

Records of daily flows at 80 stream-gaging stations located on streams on the San Joaquin Valley floor and on streams entering the valley are presented in Appendix B of this report. Measurements of flows at 175 points of diversion from major streams on the valley floor, diversions and acreage irrigated by east side irrigation districts, and deliveries from canals of the Central Valley Project are also included in Appendix B.

Hydrography

The Department of Water Resources' hydrographic activities in the San Joaquin Valley area are divided into two major categories - field and office.

The field activities include:

1. Operation and maintenance of 46 stream-gaging stations.
2. Measurement of streamflows passing the gaging stations at stages varied enough to establish a stage-discharge relationship.
3. Measurement of the quantities of water diverted by major diverters from the San Joaquin, Merced, Tuolumne, Stanislaus, and Tule Rivers, and from Dry Creek near Modesto.
4. Construction of new installations as needed to augment the base network of gaging stations operated by the U. S. Geological Survey.
5. Cooperation with public and private agencies and with other branches within the department in the gathering of hydrographic data.

The office activities include:

1. Preparation of hydrographic data for computation by machine computation methods.
2. Manual computation and compilation of the discharge of stations not adaptable to machine computation.
3. Computation and compilation of quantities of water diverted for use in quantities per month for pumped diversions and quantities per day for gravity diversions.
4. Preparation of rating curves based on a series of discharge measurements on each stream.
5. Computation of rating formulas for the curves written in machine language for machine computation purposes.

#### Hydrographic Activities of Other Agencies

The U. S. Geological Survey maintains and operates 159 streamflow stations in addition to the stations operated by the department in the San Joaquin Valley area. A number of these are operated under the Federal-State Cooperative Surface Water Measurement Program. The records are published annually in a report by the U. S. Department of the Interior, Geological Survey, entitled "Surface Water Records of California, Volume 2, Northern Great Basin and Central Valley."

The United States Bureau of Reclamation maintains and operates seven streamflow gaging stations which monitor natural inflow to the southern San Joaquin Valley. These stations are in addition to the Bureau's operation stations on project canals. Data from both types of stations appear in an annual report published by the Bureau of Reclamation entitled "Fresno Field Division Water Supply."

The U. S. Corps of Engineers, the City and County of San Francisco, and other local agencies maintain and operate stream-gaging stations within the San Joaquin Valley area. These data are published in this report. The specific degree of cooperation by these agencies with the Department of Water Resources is detailed in footnotes to tables contained in this report.

#### Runoff and Water Supply

The streams entering the valley on the east side produce the major runoff to the valley. Rainfall runoff occurs principally during the period December to April, while snowmelt is the source during the spring and summer seasons from March through June. During the summer and fall seasons, runoff is a combination of flows from perennial tributaries and releases from reservoir storage.

#### Runoff Comparisons

Runoff conditions from year to year for a particular stream are compared to the mean runoff for that stream over a long period of time. The mean runoff is a base or normal used to compare runoff with any other year. Flow conditions on all major streams entering the valley are affected by man-made impairments such as reservoirs and diversions; therefore, the runoff comparisons are made with computed natural runoff which allows for effects of impairments. These computed natural or unimpaired runoffs are considered to be the flows that would occur if no impairments were above the points of measurement. Runoff normals are computed for the 50-year period October 1907 through September 1957.

The annual unimpaired runoff in percent of average for the 50-year normal for the period 1923 through 1963 on the major streams tributary to the San Joaquin Valley is shown in Table 4. The monthly unimpaired runoff for 1963 in percent of average based on the same 50-year period is shown for the same streams in Table 5.

The water supply available during the 1963 season was above normal on all major tributaries with the exception of the Tule River which was 89 percent of normal.

(c) Percent figures are preliminary figures supplied by Water Supply and Snow Surveys, Division of Operations.

### Lakes and Reservoirs

There are 59 principal reservoirs in the State, of which 25 are located in the San Joaquin Valley area. These 25 have a total storage capacity of 4,727,520 acre-feet. The storage capacity, water in storage on October 1, 1962, and storage on October 1, 1963, in the major reservoirs in the San Joaquin Valley area are shown in Table 6. The quantity of water in storage in these 25 reservoirs at the end of the 1962-63 season was about 49 percent of the total storage capacity as compared to 36 percent at the end of the 1961-62 season.

TABLE 6

#### SUMMARY OF PRINCIPAL RESERVOIR STORAGE IN THE SAN JOAQUIN VALLEY

(In acre-feet)

Watershed	Reservoir	Total Capacity	In Storage Oct. 1, 1962	In Storage Oct. 1, 1963
<u>Stanislaus</u>	Relief	15,560	5,788	4,400
	Strawberry	18,270	10,429	10,480

<b>TOTAL</b>		4,727,530	1,721,330	2,308,401

### Streamflow Measurements

The records of many of the stream-gaging stations reported in Appendix B are maintained and operated by agencies cooperating with the Department of Water Resources. The methods used by all cooperating parties are standardized and the results obtained are equally good.

During the 1963 season 46 of the total of 80 gaging stations on streams for which records are reported herein were maintained, operated, rated, computed, and compiled by the Department of Water Resources.

### Recorders

An automatic water stage recorder is in operation at each gaging station in the San Joaquin Valley area. The continuous record of water surface elevation at each station serves two major purposes in the preparation of the data in this report, and assists in the planning of flood control projects. First, the water surface elevation (gage height) is a factor in determining the quantity of flow of the stream in

second-feet passing a given station. Second, the actual surface elevation at two adjacent stations on a stream afford the means of obtaining the water surface elevation at pumping plants along the stream between the stations. This information assists in the determination of the pumping head in order that the rate of diversion by the pumping plants can be obtained.

#### Ratings

A streamflow rating is made for each stream-gaging station. This rating gives the flow in second-feet for each gage height at the station. Normally, the gage-height-flow relation or rating is more or less permanent where there is a fixed channel and a fixed flow regimen at the station. The rating varies, however, where the bed of the channel consists of loose, shifting sand, where heavy weed growth accumulates as the season progresses, or where there may be backwater effects due to ice or other downstream conditions. In these latter cases more frequent measurements of flow are made to obtain accurate records of flows passing the station.

#### Use of Water for Irrigation

The prevailing warm temperatures and a prolonged frost-free period during the summer season in the San Joaquin Valley favors the profitable production of a wide variety of marketable crops.

The major irrigated crops in the San Joaquin Valley include rice, alfalfa, orchard fruits, nuts, grapes, cotton, corn, grain, flax, pasture grasses, and a large variety of truck crops.

#### Criteria

The number of diversion points measured on the major streams in the San Joaquin Valley may vary from year to year. The criteria for selecting points to be measured were established in 1960. At that time it was determined that by measuring only those diversion points which had an average of two hundred acre-feet per season based on the previous three years of diversion record, 50 percent of the field work could be eliminated and still 95 percent of the total water diverted could be measured.

Changes in crop pattern and the available water supply are major factors that influence the amounts of water diverted for irrigation purposes.

#### Irrigation Diversions

Measurements and records of diversions in 1963 included all the major points of diversion on the valley floor along the San Joaquin River and tributaries; along the Stanislaus, Tuolumne, and Merced Rivers, and Dry Creek tributary to Tuolumne River; and along the Tule River.

This report contains records for a total of 170 points of diversion. Table 7 shows, by streams, the number of points of diversion and the acre-feet diverted.

TABLE 7  
SUMMARY OF DIVERSION POINTS AND TOTAL ACRE-FEET DIVERTED  
Oct. 1, 1962-Sept. 30, 1963

Stream	Number Of Points Measured	Total Acre-feet Diverted
San Joaquin River		
Vernalis to Fremont Ford Bridge	39	169,800
Fremont Ford Bridge to Gravelly Ford (a)	16	865,800
Gravelly Ford to Friant Dam	24	9,583
Tuolumne River	22	14,630
Stanislaus River	23	43,170
Merced River	34	56,750
Dry Creek (Tributary to the Tuolumne River)	3	1,368
Tule River	7	54,470
TOTAL	170	1,212,571

(a) Records furnished by U. S. Bureau of Reclamation.

Waters diverted by Central Valley Project canals and east side irrigation districts are shown on Table B-95.

The monthly amount of water diverted at the individual points of diversion along all the streams covered in the San Joaquin Valley area is shown along with the total acre-feet diverted for the season in Appendix B, Tables B-86 through B-93 of this report. The monthly use in percentage of seasonal total is also shown. The location of each diversion point on a given stream is measured from the mouth of that stream, progressing upward by river-mile. References to left or right bank assume an orientation facing downstream.

All of the diversions are accomplished by pumping except for 18 by gravity. The records of diversion by gravity are obtained by means of canal ratings established by flow measurements. The records of pumping diversions are obtained in a few instances by means of canal rating but, in the main, are obtained by actual measurement of the pump discharge. Most of the pumps are electrically operated, making it possible to establish a relationship between water pumped and power input. Sufficient measurements are made to establish a rate of discharge for each pump, and the electric meters are read monthly to determine the power used.

The monthly amount of diversions in acre-feet by the large east side irrigation districts from the Stanislaus, Tuolumne, and Merced Rivers during the 1963 season is shown in Appendix B, Table B-94. The monthly amount of diversions in acre-feet by the Friant-Kern and Madera Canals from Friant Reservoir on the San Joaquin River is shown in Appendix B, Table B-95.

Fresno Slough and James Bypass normally convey excess flood flows from the Kings River into the San Joaquin River at a point above Mendota Dam, but during the irrigation season, San Joaquin River water is backed up through those channels by the Mendota Dam to afford irrigation supplies to the James and Tranquillity Irrigation Districts and to certain other diverters. The diversion data for these streams shown in Table B-87 were furnished by the U. S. Bureau of Reclamation.

#### Imported Water

Water is imported to the San Joaquin Valley from the Sacramento-San Joaquin Delta via the Delta-Mendota Canal. The amount of water diverted and its distribution for use are shown in Table B-95.

CHAPTER IV  
GROUND WATER MEASUREMENTS

Introduction

The ground water resources of California have long been recognized as one of the major natural resources of the State. The ever-increasing rate of draft on the ground water basins makes the problems associated with the use and conservation of this resource numerous and complex, and the solution more urgent.

More than one-quarter of all the ground water pumped for irrigation in the United States is used in the San Joaquin Valley. Widespread pumping began about 1900 and, especially since 1940, has increased at an accelerated rate. In response to this heavy withdrawal, ground water levels in extensive areas of the valley have declined rapidly. The water level decline will continue as long as ground-water pumpage exceeds the natural and artificial recharge of the ground water basin.

Ground water occurs under confined and unconfined conditions in the San Joaquin Valley. In much of the western, central, and southeastern parts of the valley, three distinct ground water reservoirs are present. In downward succession there are (1) a body of unconfined and semiconfined fresh water in alluvial deposits of recent, Pleistocene, and possibly later Pliocene age overlying the Corcoran Clay Member of the Tulare Formation; (2) a body of fresh water confined beneath the Corcoran Clay Member which occurs in alluvial and lacustrine deposits of late Pliocene age or older; and (3) a body of saline connate water contained in marine sediments of middle Pliocene or older age which underlies the freshwater body throughout the area. (U. S. Geological Survey Water-Supply Paper 1618 Abstract.)

In much of the eastern part of the valley, especially in the area of the major streams, the Corcoran clay member is not present and ground water occurs as one fresh-water body to considerable depth. Ground water is replenished by infiltration of rainfall, by infiltration from streams, canals, and ditches, by underflow entering the valley from tributary streams and from canyons, and by infiltration of excess irrigation waters.

The ground-water storage capacity of the San Joaquin Valley to a depth of 200 feet has been estimated to be approximately 93 million acre-feet, equal to roughly 9 times the capacity of the present and proposed surface-water reservoirs in the valley.

All studies of ground-water problems and plans for solution of these problems have two factors in common: they must be founded upon records of water level measurements and quality analysis of water samples obtained over a period of years.

The Department of Water Resources began the collection of ground-water level data in 1930 in connection with special investigation of water resources of specific areas, and has gradually developed a continuous program of basic water level data collection. Through cooperative activities of the federal and local agencies, coordinated and augmented by the department, the program of annual, semiannual, and monthly measurements of ground-water levels has gradually expanded.

Scope

The area covered by this report and its geographical relation to the Central Valley Drainage Basin are shown on Plate B-1.

The areal scope of Appendix C of this volume is depicted on Plates C-1 through C-6. During the period July 1, 1962, to June 30, 1963, the San Joaquin Valley Branch of the Department of Water Resources obtained approximately 13,000 water level measurements on some 7,500 wells. The period of record for many of these wells ranges from one to over 40 years.

Basic Data

Because significant trends in water level fluctuations can be indicated by a representative sample, a selection was made of approximately 600 wells for which the records are presented in Appendix C of this volume. These wells, designated as selected wells, were chosen on the basis of a number of factors such as

areal distribution; length of water level record; frequency of measurements; conformity with respect to water level fluctuation in the ground water area; and availability of a log, mineral analysis, and/or production record. Table C-1 presents the water level measurements made from July 1, 1962, through June 30, 1963. This volume continues the records for those wells published in Bulletin 77-62 which fall within the boundary of the San Joaquin Valley area.

#### Processed Data

Hydrographs depicting average water level fluctuations in 19 selected ground water areas are presented on Plate C-7. Individual well hydrographs depicting graphically the fluctuation of water levels are shown on Plate C-8. These wells distributed among significant areas were selected insofar as possible to be representative of their respective areas.

A ground-water map showing lines of equal elevation of water in wells for spring of 1963 appears on Plate C-9. Where sufficient data are available, lines of equal elevation of water are shown for the unconfined or semiconfined aquifer, and the confined aquifer or pressure surface.

Maps showing the areas where the ground-water level changed five feet or more in the unconfined, semiconfined, and confined aquifers are presented in Plates C-1 and C-2.

#### Related Information

For some basins or areas, maps showing depth to ground water are also prepared. At appropriate times, commonly every five years, maps are prepared showing lines of equal change occurring in the water level in wells during the time intervals. These maps are available in the office of the San Joaquin Valley Branch of the Department of Water Resources, and will be presented in future reports.

#### Cooperative Programs

The Department of Water Resources has cooperative ground water programs with the U. S. Geological Survey, U. S. Bureau of Reclamation, Kern County, Kings County Water District, and the Poso Soil Conservation District.

#### Monthly Program

Approximately 350 selected wells are measured monthly and the resulting figures are published in a monthly summary report. These wells were selected as being representative of their respective areas. Most of the field work is done by cooperating agencies, while the department measures 36 of the 350 selected wells. The department compiles and publishes the collected field data in a monthly report. The water level measurements on the selected monthly wells are included in Appendix C of this volume.

#### Annual and Semiannual Programs

In Kern County approximately 1000 wells are measured semiannually under a cooperative agreement between the U. S. Bureau of Reclamation, the Kern County Surveyors office, and the Department of Water Resources, with approximately 500 additional water level measurements being made by the Kern County Land Company and made available to the department.

Maps of Kern County showing lines of equal depth to water and lines of equal elevation of water in wells are prepared for both spring and fall of each year.

In the Kings County Water District approximately 325 selected wells are measured semiannually by that agency and submitted to the department for use in preparation of ground water maps under a cooperative agreement. Ground water maps are prepared for both spring and fall showing lines of equal elevation of water in wells in the district.

In the Poso Soil Conservation District approximately 40 wells are measured by that agency and submitted to the department. Ground water maps are prepared for the district showing depth to water in wells in January and July.

# Ground Water Conditions

Data are presented in this report for two zones or aquifers in nine of the 46 areas reported in Appendix C.

During the period July 1962 to June 1963, 28 areas in the San Joaquin Valley showed a rise in the unconfined and semiconfined aquifers. There was no change in one area, but in 13 other areas there was a decline. Six of the eleven areas for which the pressure surface is reported show a decline and five show a rise in the water level.

In the shallow zone the maximum declines occurred in the Vandalia Irrigation District and the Shafter-Wasco Irrigation District, where changes of 10.9 feet and 9.1 feet respectively are noted. The greatest rise in the shallow zone was 11.2 feet in the Lindsay-Strathmore Irrigation District. The maximum decline of 23.6 feet occurred in the Mendota-Huron area deep zone. The greatest rise in the deep zone was 23.5 feet in the Corcoran Irrigation District. In those areas for which water levels are based on a composite of shallow and deep zones, the main change was a decline of 6.8 feet in the Buena-Vista Water Storage District.

Table 8 presents a summary of ground water level data collected in the San Joaquin Valley by basin or area.

Table 9 presents the average change in ground water levels, spring 1962 to spring 1963, and the wells showing the maximum and minimum depth to ground water in the spring of 1963, for each basin or area.

The average change in water level for each basin or area was determined where possible by planimetry of ground water contour maps. In areas where insufficient data were available to define reliable contours, a numerical average was made from the actual well measurements.

<sup>6/</sup> Fall 1941 to fall 1951.

CHAPTER V  
SURFACE WATER QUALITY

Introduction

The Department of Water Resources maintains a program of surveillance of the quality of water to detect any degradation of the surface waters of California due to contributions of wastes by agricultural, industrial, and municipal water users and to notify the proper control agencies of any such occurrences. The Surface Water Quality Monitoring Program was initiated to meet this surveillance need in April 1951 with the following objectives: (1) to determine the quality of the State's surface waters through a network of strategically located sampling stations representative of the major surface streams and lakes; (2) to detect changes in the quality of surface waters and notify control agencies of adverse changes; (3) to determine trends in surface water quality; and (4) to compile data into readily available form for distribution to cooperators and interested agencies.

Scope

The areal extent of activities discussed in this chapter and in Appendix D is shown on Plate D-1. Data on the quality of surface waters are presented in graphs and tables in Appendix D for the 1963 water year (October 1, 1962, to September 30, 1963). These data represent the observed physical, chemical, bacteriological, and radiological characteristics of water collected at the surface water quality stations shown also on Plate D-1. The stations are listed alphabetically in Table D-1 and are listed in Table 11 by river units within the valley's two drainage basins, the San Joaquin River Basin and the Tulare Lake Basin.

Sampling Program

The Department of Water Resources has 29 surface water quality monitoring stations in the San Joaquin Valley area. Of these, 19 are sampled monthly, eight quarterly, and the remaining two semiannually. The variation in the sampling frequency is dependent upon past records, need, and the type of data required.

The U. S. Army Corps of Engineers and the City and County of San Francisco (Oakdale office) cooperate by the collection of samples obtained at nine and five stations, respectively.

Station Sampling

Sampling at each station consists of obtaining water samples for partial mineral and bacteriological analyses and field data including pH, temperature, gage height, and dissolved oxygen determination. The samples collected in May and September are subject to: (1) complete mineral analysis, (2) bacteriological analysis, (3) radiological analysis, and (4) determination of concentrations of phosphate, arsenic, and detergents (alkyl benzene sulfonate-ABS). A heavy metal sample is collected twice a year at ten selected stations for spectrographic analysis. The results of the spectrographic analyses for the ten stations are contained in Table D-32.

Conductivity Recorders

Conductivity recorders are installed at selected surface water stations to obtain continuous records of the specific electrical conductance of the waters. The recorder charts are removed, edited, and processed at the end of each month. The data are converted and tabulated into mean hourly and weekly electrical conductivity values. A plot of the mean weekly values versus time for each of these stations is shown on Plate D-2.

Information from these recorders is used to approximate concentrations of several water quality parameters, including concentrations of total dissolved solids (TDS), chlorides, sulfates, and total hardness. These approximations are possible because of the relationship between specific conductance and each of the above parameters.

CHAPTER VI  
GROUND WATER QUALITY

Introduction

Water development to meet the needs of California's phenomenal growth is one of the major problems facing the State. Although the use of ground water has been, and is, one of the major factors contributing to the economy of the State, insufficient data are available regarding the mineral quality of such ground water supplies. The present widespread dependence upon ground water requires constant vigilance, coupled with remedial action where necessary, to assure that the quality of ground water remains suitable for all intended uses. In view of this need, a statewide program of observation and study of ground water quality was initiated by the Department of Water Resources in 1953.

Scope

The areal scope of the activities discussed in this chapter and in Appendix E of this volume is shown on Plate E-1. Approximately 415 wells were sampled throughout the San Joaquin Valley, Panoche Valley, Tehachapi Valley and Cummings Valley. Panoche Valley was added to the monitoring program in 1960 as part of the continuing study of ground water basins of California. Tehachapi and Cummings Valleys were added in 1963 subsequent to a report by the Department of Water Resources on "A Water Supply for the Tehachapi Institution for Men," August 1961, which established the need for ground water quality data in the area. The location of the monitored wells for 1963 are shown on Plate C-3, "Location of Selected Wells."

Ground Water Quality Conditions

Adequate monitoring of the quality of a ground water basin requires the establishment of norms from which deviations can be determined. Considerable information has been gathered during the early years of this program and through other programs where ground water quality data were collected to assist in establishing the norms. Individual wells for the monitoring program were selected by an evaluation of well drillers' logs, water analyses, and water level data to best represent the quality of the ground water in the surrounding area. The number of wells needed to satisfy this objective was mainly determined by the complexity of the ground water basin in a given area. The analyses of samples collected from selected wells in the San Joaquin Valley for the 1963 water year are contained in this report. Included are tables of complete and partial mineral analyses, heavy metal and radiological determinations. The type of analysis made on a sample from a well is based mainly on the history of the data on that well.

Data collected during the 1963 water year were used to determine the quality of the main body of ground water in the San Joaquin Valley area. Plates E-2 and E-3 show the areal distribution of ground water quality characteristics in the San Joaquin Valley area. Plate E-2, "Lines of Equal Electrical Conductivity in Ground Water," depicts the variation in the concentration of dissolved minerals in ground water, as measured by electrical conductivity. Plate E-3, "Mineral Types of Ground Water," shows the areal variation of the chemical character of ground water in the San Joaquin Valley. The chemical character classification is determined by the predominant cation and anion. Wells that deviate from the norm for the reporting period are listed on Table 12.

Samples of various wells throughout the valley, especially on the west side, indicate increasing electrical conductivity (EC). This could be caused by many factors: pollution by highly mineralized waste discharges, heavy pumping in the deep zones causing connate waters to be drawn up, and/or heavy pumping in the shallow zones causing a drawdown of percolating irrigation and drainage waters containing high salts. On the other hand, importation of good quality water often reduces the concentration of salts by dilution in shallow aquifers and by reduction of ground water withdrawal.

High concentrations of nitrates occur in various places throughout the valley, both naturally and as a result of pollution. Pollution abatement in this regard is important; however, the differentiation between natural nitrates and nitrates resulting from pollution is difficult. Lithium, a relatively rare constituent of ground water, usually appears in very small quantities. In concentrations greater than

---

1 - EC = Electrical Conductivity in micromhos

2 - Radioactivity in picocuries per liter

3 -  $\pm X$  is statistical deviation (0.9 confidence level)

4 - NO<sub>3</sub> = Nitrates

5 - ppm = parts per million

6 - value not exact due to interference in determination

7 - ABS = Alkyl-Benzene-Sulfonate (Detergents)

0.1 part per million, however, lithium has been found to be detrimental to citrus and other fruit trees in much the same manner as boron. Arsenic and copper, although generally rare, also are found in some ground waters of the valley and can be significant in small concentrations.

Detergents (ABS: alkyl benzene sulfonate) have been determined to be an indicator of pollution and therefore should not occur in ground water. For this reason ABS determinations are made on samples from wells in the vicinity of sewage or industrial waste discharges. Although no critical values of radioactivity have been reached in the valley, certain wells have had higher than normal values. These could be naturally occurring conditions or pollution from radioactive sources.

#### Sampling Program

Samples from the monitored areas are collected from early spring, when pumping begins, through the fall, when pumping generally slows down. Most of the samples collected are obtained by cooperating agencies, the remainder being obtained by the department. Table 13 lists the agency, the corresponding area, and the number of wells sampled by that agency.

## INTRODUCTION

This appendix presents the climatological data for the period July 1, 1962, to June 30, 1963. The data consists of precipitation station descriptions, monthly precipitation quantities, monthly temperature summaries and monthly evaporation totals.

## EXPLANATION OF TABLES

### Precipitation Station Index

Table A-1 shows the precipitation station index. The climatological station designations used are based on the drainage basin and alpha number. Stations are also named and latitude and longitude are shown to the nearest minute. The county, elevation above sea level, the year the record began and the name of the current observer of record is also shown.

Each main drainage basin is assigned a letter and each subbasin a number as shown on Plate A-1 of this report.

The alpha order number is assigned each station to denote its order in alphabetical sequence for machine processing. The subnumbers are used to avoid duplication of the original four-digit system for machine processing. Only 21 columns are available for the station name making some abbreviations necessary.

Each station is generally named after and referenced to the nearest post office (Livingston 5W - a point 5 miles west of the post office in the town of Livingston), or named for a geographic location (Chiquito Creek). Occasionally the observer's name is incorporated in the station name (Hornitos Giles Ranch).

### Monthly Precipitation

Table A-2 shows the monthly and seasonal total rainfall for some 395 weather stations within and near the San Joaquin Valley area. This table summarizes all of the available precipitation observations from July 1962 through June 1963. Daily records are available in department office files.

### Monthly Temperatures

Table A-3 shows a temperature summary for a monthly period at 60 weather stations throughout the San Joaquin Valley area.

The individual observations were obtained using the observations, techniques, types of thermometers, and exposure conditions recommended by the U. S. Weather Bureau. The Fahrenheit scale is used in all references to temperature.

Terms used in connection with the temperature data are explained in the following:

<u>Term</u>	<u>Definition</u>	<u>Abbreviation</u>
Maximum	The highest temperature of record for the month	Max.
Minimum	The lowest temperature of record for the month.	Min.
Average maximum	The arithmetic average of daily maximum temperatures for indicated period.	Avg. max.
Average minimum	The arithmetic average of daily minimum temperatures for indicated period.	Avg. min.
Average temperature	The average of the daily maximum and minimum for each day; the daily averages are averaged to make the monthly averages.	Avg.

### Monthly Summary of Evaporation Station Data

Table A-4 shows the monthly net evaporation at 12 stations throughout the San Joaquin Valley area.

Observations of the amount of water evaporating from an open pan are made in the manner recommended by the U. S. Weather Bureau. The standard Weather Bureau pan is 47.5 inches in diameter and

10 inches deep. It contains clean water to a depth of 7 to 8 inches. The pan is placed on a lumber frame to insulate it from significant conductive heat exchange with the ground. The evaporation is measured by the actual difference in the pan water surface elevation over a 24-hour period with the appropriate adjustments for rainfall.

Terms used in connection with evaporation data are explained below:

<u>Term</u>	<u>Definition</u>	<u>Abbreviation</u>
Evaporation	The net amount of water evaporated from the pan for the period given.	Evap.
Precipitation	The total amount of rainfall in inches which occurred during the period.	Precip.
Wind	The total movement of air over the pan, in miles, for the period.	Wind
Average maximum	See explanation in temperature data table.	
Average minimum	See explanation in temperature data table.	

#### Reference Notes

A list of the reference notes used in the climatological portion of this report follows:

CD Record published in "Climatological Data" by U. S. Weather Bureau.

WB All or part of record published by U. S. Weather Bureau.

HPD Record published in "Hourly Precipitation Data" by U. S. Weather Bureau.

HPD CD Published in both "CD" and "HPD" from separate gages. Record from "CD" reproduced in this report.

CD(P) Precipitation data published in "CD". Other data published by DWR.

R CD Published in both "CD" and "HPD" from recording rain gage. Record from "CD" reproduced in this report.

R Recording rain gage. Hourly precipitation distribution not necessarily available at DWR.

(R) Hourly precipitation record also available for this station.

S Storage gage. Data published in "Storage Gage Precipitation Data" by U. S. Weather Bureau.

Ss Storage gage using standard rain gage. Data published by DWR.

T Trace.

AS After storm only. Small amounts may not be recorded.

b Preliminary data - subject to revision.

E Wholly or partially estimated.

- No record.

M All or part of record missing.

RB Beginning of record.

RE End of record.

\* Amount included in following measurement; time distribution unknown.

V Includes total for previous month.

D Water equivalent of snowfall wholly or partly estimated using a ratio of 1 inch water equivalent to every 10 inches of new snowfall.

SCE Data obtained from Southern California Edison Company.

Additional criteria are:

Dimensional units used in this report are: Temperature in degrees Fahrenheit, precipitation and evaporation in inches, and wind movement in miles (per month).

Evaporation, wind movement and temperature data in this report are not published by the U. S. Weather Bureau.

All temperature data represent air temperatures.

## INTRODUCTION

This appendix presents surface water data for the Water Year 1963 which is from October 1, 1962, to September 30, 1963. The data presented in this appendix consists of daily mean discharge, station locations, daily mean gage heights, and diversion quantities.

Stream gaging station descriptions presented show the historic maximum discharge of record and the maximum discharge for the report year. Locations of the gaging stations and other important data on the length of record and datum of gage are also presented.

Quantities of daily mean discharge for most stations shown are computed by an electronic computer. The gage height data are fed into the computer simultaneously with rating and shift correction data. Daily mean discharge, total monthly acre-feet, and instantaneous maximum and minimum discharge are computed. The gage height data are extracted from the standard recorder chart by a semiautomatic chart-reading machine and put into machine language. The record for those stations affected by backwater conditions is not adaptable to computation by machine methods and is computed manually by standard methods.

Daily mean stage tables are presented for key stations on the major streams in the San Joaquin Valley. These daily mean stages are computed by the electronic computer, as mentioned above. The gage heights are computed to the nearest one-hundredth of a foot, and the major crests for the year are shown.

Quantities of water diverted for use are shown as monthly total acre-feet and total acre-feet diverted for a certain reach of a stream.

### Definition of Terms

A list of definition of terms as used herein follows:

Second-foot or cubic foot per second is the unit rate of discharge of water. It is a cubic foot of water passing a given point in one second.

Acre-foot is the quantity of water required to cover one acre to a depth of one foot. It is equivalent to 43,560 cubic feet or 325,850 gallons.

Drainage area of a stream above a specific location is that area, measured in a horizontal plane, which is enclosed by a drainage divide.

Unimpaired runoff is the flow that would occur naturally at a point in a stream if there were: (1) no upstream controls such as dams and reservoirs; (2) no artificial diversions or accretions; and (3) no changes in ground water storage resulting from development. Unimpaired flow is computed from measured runoff by allowing for man-made changes in natural conditions.

Water Year is the 12-month period from October 1 of any year through September 30 of the subsequent year and is designated by the calendar year in which it ends.

### Surface Water Gaging Station Designation

The index number for each gaging station is composed of a number which begins with an alphabetical letter designating the hydrographic area, followed by the first digit which indicates the main river basin. The second digit refers to a tributary of the main river basin. The hydrographic area and the river basin are outlined on Plate B-1. The remaining three digits are used to number stations in an upstream direction with the lowest number at or near the mouth. The digit 9, which is the third from the left, indicates that the station is a surface gravity diversion station. Each station is listed by name as well as by machine index number.

## EXPLANATION OF TABULAR DATA

The tabular data presented in this appendix are divided into the general categories of daily mean discharge, daily mean stage, and monthly diversions.

The area to which these data pertain is shown as Area 4 on page iii and on Plate B-1.

Table B-1 presents gaging station additions and discontinuations; it also presents revisions to previously published reports.

### Lakes and Reservoirs

Three types of data are presented for lakes and reservoirs. Table B-2 presents inflow to Millerton Lake. Table B-3 presents the daily content of Millerton Lake in thousands of acre-feet. Table B-59 presents daily mean gage height of Tulare Lake.

### Daily Mean Discharge

Presented in Tables B-4 through B-58 are records of daily mean discharge, gaging station location, period of record, maximum flow of record, maximum and minimum flow for the season, as well as the total flow in acre-feet for the 1962-63 water year.

The streamflow tables are arranged, for each stream or stream system, in downstream order. Stations on a tributary entering between two main stem stations are listed between those stations, and in downstream order on that tributary. A stream gaging station is named from the stream and the nearest post office (Merced River at Cressy) or well-known landmark (San Joaquin River at Fremont Ford Bridge).

Each stream gaging station has a stage-discharge relationship or rating developed. The rating gives the flow in second-feet for each gage height at the station. When flows at a single station occur in excess of 140 percent of the highest measurement on the rating, the computed daily mean discharges from the electronic computer are shown as estimated. Normally, the rating is fairly permanent where there is a fixed channel and a fixed flow regimen at the station. The rating varies, however, where the bed at the channel is of loose shifting sand, or where aquatic growth builds up in the channel changing the flow regimen.

Where the rating is not permanent and varies periodically, more frequent measurements of discharge are necessary to accurately determine the daily mean discharge.

All streamflow data reported herein are derived through the use of mechanical, arithmetical, and empirical operations and methods. Since the results are affected by inherent inaccuracies in the procedures and equipment used, it becomes necessary to establish limits of accuracy for which the data are reported.

The following is a listing of significant figures used in reporting streamflow data:

#### 1. Daily flows - second-feet

0.0	- 9.9	Tenths
10	- 99	2 significant figures
100	- up	3 significant figures

#### 2. Means - second-feet

0.0	- 99.9	Tenths
100	- 999	3 significant figures
1000	- above	4 significant figures

The water year totals are reported to a maximum of four significant figures.

### Daily Mean Gage Heights

Presented in Table B-59 through B-85 are records of daily mean gage heights for key stations on major streams in the San Joaquin Valley for the 1962-63 water year.

At the bottom of the stage tables are shown the major river crests occurring for the 1962-63 water year. The table also shows the location of the station, maximum gage height of record, period of record, and datum of gage. The elevation of water surface at the gaging station is obtained by adding the gage

height reading to the elevation of the gage datum presented in each table. Gage height for stage tables are computed from recorder charts and are reported to one-hundredth of a foot.

Of the 26 stations for which daily mean gage heights are presented in this report, 13 have computed daily mean discharge. These data are included in the streamflow tables.

#### Diversions

Presented in Tables B-86 through B-95 are the amounts of water diverted for irrigation during the period October 1, 1962 through September 30, 1963. The amounts of water diverted by pumping were determined by rating the capacity of each diversion pumping plant and collecting data on hours of operation. The amounts of water diverted by gravity (indicated by "Gravity" in column headed "Number and Size of Pump") were determined either by calibrating suitable measuring devices or by rating canals in a manner similar to that used to rate streamflow stations.

Because of the intermittent operation of most diversion facilities, the monthly diversion values are reported in acre-feet to three significant figures. The totals for individual water users and stream reaches are reported to four significant figures.

Station located about center of Friant Dam on San Joaquin River, immediately above Cottonwood Creek, 0.9 mi. NE of Friant. Usable capacity, 503,000 ac.-ft. between elevations 375.4 and 578.0 ft. above mean sea level. Not available for release, 17,400 ac.-ft. Inflow to Friant Reservoir takes into account change in storage, release, spill, precipitation, and evaporation, and is representative of the natural flow which would pass the dam site if the dam had not been constructed. Figures shown under total discharge are computed inflow to the reservoir. Period of record for computed inflow is shown under period of record for discharge. Records furnished by U.S.G.P. Drainage area is 1,633 sq. mi.

Station located at Tracy Pumping Plant at intake to canal, 6 mi. SE of Byron, 10 mi. NW of Tracy.  
Discharge computed from records of operation of pumps. Water is diverted from Sacramento-San  
Joaquin Delta by way of Old River and a dredged channel to the Tracy Pumping Plant where it is  
lifted about 200 ft. into canal. Records turn by U.S.B.R.

Station located 195 ft. above road culvert pipe, 1.4 mi. SE of Fish Camp. This is regulated diversion from Big Creek to Lewis Fork, Fresno River. Stage-discharge relationship at times affected by ice and extreme high flows affected by culvert pipe below station.

Maximum discharge determined from slope area survey and maximum capacity of culvert pipe below station.

Station located at Co. Rd. bridge, 5.6 mi. E. of Cathay School. Tributary to San Joaquin River. Drainage area is 66.0 sq. mi. Altitude of gage is 1100 ft. (from topographic map.)

a-Previously reported as 4530E cfs. After obtaining additional high flow discharge measurements, the stage-discharge relation for high flows was more closely defined. Maximum discharge of record adjusted to present rating. See Table B-1 for additional information.

										USCGS

This station was installed in January 1962 for the Lower San Joaquin Flood Control Project for the purpose of recording flows through the Mariposa bypass (a float actuated electrically operated gate). No continuous water stage recorder is installed to date. Miscellaneous measurements of instantaneous discharge will be presented when appropriate.

Station located below Dogtown Road Bridge, 0.5 mi. NE of Coulterville. Tributary to Merced River.  
Drainage area is 17.0 sq. mi. Altitude of gage is 1740 ft. (from topographic map.)

a-Previously reported as 956 cfs. After obtaining additional high flow discharge measurements,  
the stage-discharge relation for high flows was more closely defined. See Table B-1 for  
additional information.

Station located on left bank 30 ft. above the Durham Ferry Highway Bridge, 3 mi. below the Stanislaus River 3.4 mi. NE of Vernalis. Drainage area is approx. 14,010 sq. mi. Natural flow of stream affected by storage reservoirs, power development, ground water withdrawals and diversions for irrigation. Low flows consist mainly of return flow from irrigation. This station is operated under the Federal-State Cooperative Program. The records are furnished by the U.S.G.S.

Station located 1.6 mi. W of U.S. Highway 99, 5.8 mi. S of Tulare. Prior to Mar. 4, 1960, station located 700 feet W of U.S. Highway 99, 4.5 mi. S of Tulare. Tributary to Tule River. Prior records, 1942 to July 1953, available at a site 1 mi. E of Elk Bayou Ave. 3.6 mi. below Old Highway 99 Bridge. Recorder installed March 6, 1957. Altitude of gage is approximately 250 ft. (from U.S.G.S. topographic map).

(a) Work in control to install a gate created a condition, from 7-17-63 to 9-30-63, making it impossible to record low flows if such flow did occur.

Station located 2.2 mi. SW of Chatom Ranch, 0.1 mi. SW of Corcoran on south end of El Rico Bridge. Tulare Lake receives water from Kings, Kaweah, and Tule Rivers during high-water periods and occasionally from Kern River, Deer Creek, and several small intermittent streams. Elevation at lowest point of lake bed is now about 180 ft. U.S.G.S. datum. Records furnished by Tulare Lake Basin Water Storage District.

Station located 6.0 mi. NW of Raymond on Raymond Road. Elevation of station is approximately 600 ft. USC&S datum. This station was installed in cooperation with Madera County and Chowchilla Water District. It is a flood control warning station, equipped with a Stevens Surface Detector and Telemark. Low flows are not recorded. Prior to 1962, high flow records were insufficient for publication. Discharge measurements and partial flow records are available in DWR files. In order to machine process this station, the recorder datum was changed. To obtain true elevations add 500 feet to all of the above gage heights.

Station located 5 mi. NW of Santa Rita Bridge and 5 mi. W of El Nido. Flows sometimes affected by operation of control structures below station. During this period flows are not computed. Partial flow records and discharge measurement are available in the office of the San Joaquin Valley Branch of the Department of Water Resources. In order to machine process this station, the recorder datum was changed. To obtain true elevations add 100 feet to all of the above gage heights.

The diagram illustrates a two-dimensional lattice structure. It consists of a grid of points connected by horizontal and vertical bonds. A specific path is highlighted with a thicker line, starting from a point on the left, moving horizontally to the right, then vertically upwards, and finally horizontally to the right again. The horizontal bond length is labeled 'a' and the vertical bond length is labeled 'b'.

Station located 30 ft. below Fremont Ford Bridge, 4.5 mi. W of Stevinson, 6.7 mi. above the Merced River. During periods of high flow, some water bypasses station through Mud Slough. Maximum discharge of record is for period 1944 to date. Records furnished by U.S.G.S. Drainage area is approx. 8,090 sq. mi. Flow records are published in U.S.G.S. report, "Surface Water Records of California."

\* Mileage along San Joaquin River from its mouth, 4.5 miles below Antioch.

a One 16" unit was removed in 1963.

b Replaces a 12" unit.

c Includes an undetermined amount of water returned to river by spill.

d Formerly listed as W. F. Cook

\*\* West Stanislaus Irrigation District Canal. The intake canal joins the San Joaquin River at mile 91.3L. Distance from the river and the bank is shown in parentheses.

- \* Distance from parent to the point of diversion.
- \*\* Flow measured at gaging station on Porter Slough Ditch located approximately 150 feet below head.
- Flow measured at gaging station on Porter Slough Ditch located approximately 150 feet below head.
- Flow measured at gaging station on Vandalia Ditch located approximately 1000 feet below head. The greater portion of this water was used to irrigate Vandalia Irrigation District well field.
- Flow measured at gaging station on Poplar Ditch located approximately 4750 feet below head.
- Flow measured at gaging station on Hubs-Miner Ditch located approximately 3400 feet below head.
- The recorder at this station was deactivated during the following periods: 10-1-62 through 2-1-63 and 2-6-63 through 2-10-63. This recorder was activated prior to anticipated diversion periods upon notification from the Tule River Association. It is assumed there was no flow during these deactivated periods.

- The recorder at this station was deactivated during the following periods: 10-1-62 through 2-1-63, 3-1-63 through 4-1-63, and 8-1-63 through 9-30-63. This recorder was activated prior to anticipated diversion periods upon notification from the Tule River Association. It is assumed there was no flow during these deactivated periods.
- Flow measured at gaging station on Woods-Central Ditch located approximately 100 feet below head.
- The recorder at this station was deactivated during the following periods: 10-1-62 through 1-30-63, 2-26-63 through 6-22-63, and 8-16-63 through 9-30-63. This recorder was activated prior to anticipated diversion periods upon notification from the Tule River Association. It is assumed there was no flow during these deactivated periods.

- \* Data for Madera and Friant-Kern Canal furnished by USBP.  
 a All other data furnished by individual irrigation districts.  
 b An additional 83,209 acre-feet of water was pumped from wells.  
 c Of this acreage, 2,380 was double cropped. It does not include an undetermined amount of riparian water users acreage.  
 d An additional 114,137 acre-feet of water was pumped from wells.  
 e Of this acreage, 15,891 was double cropped.  
 f An additional 39,470 acre-feet of water was pumped from wells.  
 g Of this acreage, 10,666 was double cropped.  
 h An additional 506 acre-feet of water was pumped from wells.

- i Of this acreage, 209 was double cropped.  
 j Of this acreage, 274 was double cropped.  
 k Of this acreage, 609 was double cropped.  
 l This acreage also received 32,231 acre-feet of water from wells and controlled drainage.  
 m This acreage also received an undetermined amount of well water, and an undetermined amount of controlled drainage water from Gardale Irrigation District. Of this acreage, 3,284 was double cropped. Includes 1,935 acres served by subirrigation.

C-7	Fluctuation of Average Water Level, 1921 to 1963, in Nineteen Historic Ground Water Areas in San Joaquin Valley.
C-8	Fluctuation of Water Level in Selected Wells in San Joaquin Valley
C-9	Lines of Equal Elevation of Water in Wells, San Joaquin Valley - Spring 1963

## INTRODUCTION

This appendix presents ground water measurement data for the period July 1, 1962 through June 30, 1963.

The area for which ground water level measurements of selected wells are shown on Table C-1 is designated as Area 4 on page iii. Area 4 is that portion of the Water Pollution Control Board Region 5, which includes the Stanislaus River drainage area and the area south, to the Tehachapi Mountains.

The department cooperates with U. S. Geological Survey and the U. S. Bureau of Reclamation and many local agencies for the systematic observation of ground water levels. Wells for which water level measurements are collected in the San Joaquin Valley Hydrologic area number approximately 7,500 of which nearly 600 are presented here. These 600 wells were selected as representative wells of all the wells measured in the area, and are designated as selected wells. These wells were selected on the basis of a number of factors such as areal distribution; length of water level record; frequency of measurements; conformity with respect to water level fluctuations in the ground water basin or area, in a confined aquifer, or in a zone of shallow depth; and availability of a log, mineral analyses, and production records.

The depth to water in most wells is usually a direct measurement made with a tape; however, in some wells, especially deep ones, measurements are made with an air line and gage or an electric sounder.

Forty-six ground water basins or areas in the San Joaquin Valley are shown on Plates C-1 and C-2.

The districts or areas with a ground water level change of five feet or more in the unconfined and semiconfined aquifers are also shown on Plate C-1. The districts or areas with a ground water level change of five feet or more in the confined aquifers are shown on Plate C-2.

A map showing the location of the selected wells as listed in Table C-1 is presented on Plate C-3.

Outlined on Plate C-4 is the Poso Soil Conservation District Cooperative Ground Water Program area.

Presented on Plate C-5 is that portion of Kern County covered in the Kern County cooperative ground water program for that area.

## Definitions

Free ground water - Water in the interconnected interstices in the zone of saturation down to the impervious barrier, moving under the control of the water-table slope.

Confined ground water - A body of ground water overlain by material sufficiently impervious to sever free hydraulic connections with overlying ground water except at the intake. Confined water moves in conduits under pressure due to difference in head between intake and discharge areas of the confined water body.

Pressure surface - Or piezometric surface is the level to which the water level will rise above the bottom of a confining bed of impervious material when penetrated.

Perched ground water - Ground water occurring in a saturated zone separated from the main body of ground water by unsaturated material.

Water table - On pervious granular material the water table is the upper surface of the body of free water which completely fills all openings in the material sufficiently pervious to permit percolation. On fractured impervious rocks and in solution openings, it is the surface at the contact between the water body in the openings and the overlying ground air.

A map of 19 historic ground water areas and profiles along a section showing water levels in 1921, 1951, 1962, and 1963 are presented on Plate C-6.

Unit hydrographs depicting the fluctuation of average water levels in the 19 historic ground water areas in the San Joaquin Valley are presented on Plate C-7.

Water level fluctuations are depicted graphically on hydrographs for 35 selected wells distributed among significant basins and areas in the San Joaquin Valley. The hydrographs are presented on Plate C-8 by region, basin, or area, and well number.

Presented on Plate C-9 is a map showing lines of equal elevation of water in wells, San Joaquin Valley, Spring 1963.

#### RECORDS OF GROUND WATER LEVELS AT WELLS IN THE SAN JOAQUIN VALLEY

##### Explanation of Headings and Symbols Used in Columns in Table C-1

State Well Number--The well numbering system used in this report is based on the township, range, and section subdivision of the Public Land Survey. It conforms to the system used in all ground water investigations and for numbering all wells for which data are published or filed by the Department of Water Resources. In this report the number, which is assigned to a well in accordance with this system, is referred to as the "State" well number.

Under the system, each section is divided into 40-acre tracts lettered as follows:

D	C	B	A
E	F	G	H
M	L	K	J
N	P	Q	R

Wells are numbered within each 40-acre tract according to the chronological sequence in which they have been assigned State Well Numbers. For example, a well which has the number 16S/15E-17K1 M would be in Township 16 South, Range 15 East, Section 17, M.D.B. & M., and would be further located as the first well assigned a State Well Number in Tract K. In this report, well numbers are referenced to the Mount Diablo Base and Meridian (m) or the San Bernardino Base and Meridian (S).

Ground surface elevation--The numbers in this column give the elevation in feet above mean sea level (U.S.G.S. datum).

Date--The date shown in this column is the date upon which the depth measurement given in the next column was made.

Ground surface to water surface in feet--This is the measured depth in feet from the ground surface to the water surface in the well. Certain of the depth measurements in the column may be followed with an asterisk superscript to indicate a questionable measurement. Depth to ground water measurements may be questionable for such reasons as (a) well being pumped while undergoing measurement, (b) nearby pump operating, (c) casing leaking or wet, (d) well pumped recently, (e) air gage measurement, (f) recharge operation at well or nearby. The specific reason for any asterisk on any given measurement may be obtained through the San Joaquin Valley Branch Office of the Department of Water Resources.

Other code symbols used in this column are as follows:

- - No measurement
- ⊖ - Measurement discontinued
- ⊙ - Well has been destroyed

The words FLOW and DRY are shown in this column to indicate a flowing or dry well, respectively.

The word DISCONTINUED indicates records from this well will no longer be published.

Water surface elevation--This is the elevation in feet above mean sea level (U.S.G.S. datum) of the water surface in the well. It was derived by machine computation by subtraction of the depth measurement from the reference point elevation.

Agency supplying data--The numbers in this column are the code numbers for the agencies supplying water level data. The agency code consists of a five-digit number, the first of which is a region number. Thus, 54200 refers to agency 4200 in Region 5. Because of the limitations of punch-card space, the agency code has been shown as a four-digit number without the region number.

The first digit of the four-digit agency code designates the type of well numbering system used by the agency as follows:

<u>Code</u>	<u>Well Numbering System</u>
4	Local numbers
5	State or U. S. G. S.
6	U. S. B. R.
7	South San Joaquin Irrigation District
8	Kern County Land Company

The last three digits of the agency code are numbers that designate, within specified serial limits, the type of agency from which the data were obtained, as follows:

<u>Code</u>	<u>Type of Agency</u>
000-049	Federal
050-099	State
100-199	County
200-399	Municipal
400-699	District--Water, Irrigation, Conservation, etc.
700-999	Private

In the Central Valley Region, the agency code for districts is further broken down to the geographic areas, as follows:

<u>Code</u>	<u>Area in Central Valley Region</u>
500-599	American River to San Joaquin River
600-699	San Joaquin River to Tehachapi Mountains

In this list of water levels, the agency furnishing the measurement is listed. The agencies and code numbers assigned to them are as follows:

<u>Agency Code</u>	<u>Agency</u>
4200	City of Fresno
4520	Oakdale Irrigation District
4521	Modesto Irrigation District
4524	Turlock Irrigation District
4525	Merced Irrigation District
4636	Consolidated Irrigation District
4637	Alta Irrigation District
4640	Buena Vista Water Storage District

<u>Agency Code</u>	<u>Agency</u>
5000	U. S. Geological Survey
5050	Department of Water Resources
5120	Kern County Surveyor
5529	Poso Soil Conservation District
5631	Fresno Irrigation District
6001*	U. S. Bureau of Reclamation
7518	South San Joaquin Irrigation District
8700	Kern County Land Company

\*A large amount of data listed under this agency code has been gathered by irrigation and water districts and compiled by the Bureau of Reclamation for transmittal to the Department of Water Resources.

D-2	Weekly Mean Specific Conductance at Selected Stations

## INTRODUCTION

This appendix contains data pertaining to the quality of surface waters collected during the 1963 water year (October 1, 1962 to September 30, 1963). The data are presented as tables and graphs and represent the observed physical, chemical, and bacteriological characteristics of the waters collected at the surface water quality monitoring stations.

The stations are sampled periodically (monthly, quarterly, or semiannually), depending on past records, need, and the type of data required for each station. Samples collected and the field data obtained at the stations are as follows:

1. Partial mineral analysis -  $\frac{1}{2}$  gallon
2. Bacteriological analyses (coliform) - 2 samples in 4 oz., sterilized bottles
3. Dissolved oxygen - D.O.
4. pH
5. Temperature
6. Gage Height
7. Time
8. Visual observation of water conditions

In May and September, the partial mineral analysis is replaced by a complete mineral analysis and the following are added to the list above:

1. Radiological analysis
2. Phosphate, arsenic and detergents (ABS)
3. Spectrographic analysis of heavy metals (for ten selected stations)

Continuous conductivity recorders are installed at six of the surface water quality monitoring stations, as indicated on Plate D-1. The recorders measure specific electrical conductance, a characteristic of water which provides an approximation of the quantity of minerals in solution.

## EXPLANATION OF TABLES

An alphabetical listing of all stations in the surface water monitoring program is found in Table D-1 along with information concerning station number and location, period of record, frequency of sampling, and agency responsible for collection of samples.

Results of mineral analyses can be found in Tables D-2 to D-31, where mineral concentrations, dissolved oxygen, and ABS are expressed in parts per million (ppm). Discharges are expressed as cubic feet per second (cfs) and bacteriological determinations are expressed as the most probable number (MPN) of coliform bacteria per milliliter of sample.

Results of spectrographic analyses for heavy metals, found in Table D-32, are expressed as micrograms per liter or parts per billion.

Table D-33 contains results of radiological analyses, expressed as picocuries per liter (pc/l).

## EXPLANATION OF PLATES

Locations of surface water quality stations and recorder sites are found on Plate D-1.

Plate D-2 presents, in graphical form, data obtained from electrical conductivity recorders in terms of mean weekly values of electrical conductivity ( $EC \times 10^6$  micromhos) plotted against time (week).

## EXPLANATION OF TERMS AND ABBREVIATIONS

Cubic foot per second (cfs) - the rate of discharge of water where a cubic foot of water passes a given point in one second.

Dissolved oxygen (DO) - the amount of free oxygen contained in water. It is one of the most important indicators of the condition of a water supply.

EXPLANATION OF TERMS AND ABBREVIATIONS (Continued)

Total dissolved solids (TDS) - represents the dissolved mineral constituents in water.

Specific conductance - a measure of the capacity of water to conduct a current of electricity.

Coliform - a group of organisms, whose presence is a satisfactory bacteriological indicator of contamination or pollution in water.

Most probable number (MPN) - an index of the number of coliform bacteria which more probably than any other number would give the results shown by laboratory tests.

Hardness - a characteristic of water that determines its usefulness and economic value. It is mainly caused by compounds of magnesium and calcium and is usually recognized by the increased quantity of soap required to produce lather.

a Field pH.

b Laboratory pH.

c Sum of calcium and magnesium in ppm.

d Arsenic (As), alkyl benzene sulfonate (ABS), and phosphate (PO<sub>4</sub>).

e Derived from conductivity vs TDS curves.

f Determined by addition of analyzed constituents.

g Gravimetric determination.

h Annual median and range, respectively.

i Mineral analyses made by United States Geological Survey, Quality of Water Branch, (USGS), United States Department of the Interior, Bureau of Reclamation (USBR), United States Public Health Service (USPHS), San Bernardino County Flood Control District (SBCTFD), Metropolitan Water District of Southern California (MWDSC), California Department of Water Resources (CDWR), City of Long Beach, Department of Public Health (LBDPH), Terminal Testing Laboratories, Inc. (TTL), or California Department of Water Resources (DWR), as indicated.

j Effective July 1963, this station sampled only in January, May, July and October.

Field 04

Laboratory pH

Sum of calcium and magnesium in com.

Sum of calcium and magnesium in ppm.

Derived from conductivity vs. TDS curves

o Derived from conductivity vs IDS curves

f Determined by addition of a

g Gravimetric determination  
 a. Calculated from analyses of duplicate monthly samples made by California Department of Public Health, Division of Laboratories, or United States Public Health Service

Annual method and range, respectively. Calculated from analyses of duplicate monthly samples made by California Department of Public Health, Division of Laboratories, at United States Public Health Service Mineral analyses made by United States Geological Survey, Quality of Water Survey (USGS); United States Department of the Interior, Bureau of Reclamation (USBR); United States Public Health Service (USPHS); San Bernardino County Flood Control District (SBFCFD); Metropolitan Water District of Southern California (MWD); Los Angeles Department of Water and Power (LADWP); City of Los Angeles, Department of Public Health (LBDPH); Terminal Testing Laboratories, Inc. (TTL); or California Department of Water Resources (DWR), as indicated.

STANTISLAUS RIVER NEAR MOUTH (STA. NO. 29)

Control District (SBCFCU); Metropolitan Water District of Southern California (MWSD); Los Angeles Department of Water Services (LADS); and indicated

TABLE D-27

## ANALYSES OF SURFACE WATER

STANISLAUS RIVER BELOW TULLOCH DAM (STA. NO. 29A)

[illegible]

Field pH

Laboratory pH.

Sum of calcium and magnesium in ppm.

Arsenic (As), alkyl benzene sulfonate (ABS), and phosphate (PO<sub>4</sub>)

Derived from conductivity vs TDS curves

<sup>c</sup> Determined by addition of analyzed constituents.

Determined by addition of 0.1%

g. Gravimetric determination. Calculated from analyses of duplicate monthly samples made by California Department of Public Health, Division of Laboratories, or United States Public Health Service.

Annual median and range, respectively. Calculated from analyses of water quality compiled into a database by the United States Geological Survey (USGS), United States Department of the Interior, Bureau of Reclamation (USBR), United States Public Health Service (USPHS), San Bernardino County Flood Management Commission, and San Bernardino County Flood Control District.

**Control District (SBCFCD):** Metropolitan Water District of Southern California (MWD); Los Angeles Department of Public Works; County of Water Branch (CWB); Mineral analyses made by United States Geological Survey.

E-3	Mineral Types of Ground Water

### INTRODUCTION

This appendix contains data pertaining to the ground water quality conditions in the San Joaquin valley area. The data consist of the chemical and radiological characteristics of those waters sampled. The analyses represent those constituents determined as most significant in the evaluation and/or surveillance of ground water quality. These data are listed on tables and portrayed on plates.

### EXPLANATION OF TABLES

All data in the Appendix E Tables are listed by ground water basin or area which are shown on plate E-1. The order is by the corresponding number found under the name. Following this breakdown the wells are tabulated numerically by state well numbers as explained on page C-6.

Table E-1 lists the mineral analyses of the selected wells for the area reported in this volume. The following tabulation indicates the tests made and the properties and constituents usually determined in the two types of mineral analyses.

Constituents and properties	: A n a l y s i s :	
	: Standard :	: Partial :
	: mineral :	: mineral :
Specific conductance	x	x
pH	x	
Total dissolved solids	x	
Percent sodium	x	
Hardness	x	x
Temperature	x	x
Calcium	x	
Magnesium	x	
Sodium	x	x
Potassium	x	
Carbonate	x	
Bicarbonate	x	
Sulfate	x	
Chloride	x	x
Nitrate	x	
Fluoride	x	
Boron	x	x
Silica	x	

The standard mineral analysis is made on the samples of wells either new to the program or whose previous analyses have been unstable from year to year requiring a more complete history before partial analysis would be suitable. A partial mineral analysis is suitable when a satisfactory history on the well has been established and a detailed analysis is not required to maintain surveillance.

Heavy metal analyses are shown on Table E-2 and list other important constituents not determined in a standard mineral analysis. These constituents, though small in quantity, can be of significance for various types of water usages.

Radioassay analyses are shown on Table E-3. The type of test conducted was for gross radioactivity since the purpose is mainly for reconnaissance by random sampling and a detailed analysis is not required.

Two constituents not normally determined, ABS (detergents) and lithium, were analysed for in selected samples, and are shown on Table E-4. ABS determinations are made because of their use as an indicator of pollution. Lithium was determined in response to a request from the Kern County Farm Advisor because it has a detrimental effect similar to that of boron on citrus and other fruit trees.

Wells whose analyses differ significantly from other wells in the surrounding area are listed in Table E-5. This deviation may be in a single constituent or it may be the complete analysis. Special effort is made to investigate these wells to determine the reason for the observed deviations.

### EXPLANATION OF PLATES

The locations of the selected sampling wells and the selected wells for water measurements are shown on Plate C-3.

#### EXPLANATION OF PLATES (Continued)

The ground water basins and areas sampled during this reporting period are shown on Plate E-1 with their corresponding name and number. Plate E-2 shows the "Lines of Equal Electrical Conductivity of Ground Water" in the San Joaquin Valley. These contours are based on analyses listed on Table E-1 and represent the quality of water from the principal pumped zone in the valley. Contours were not drawn for Panosco, Tehachapi and Cummings Valleys because of the lack of data.

Plate E-3 shows the types of water in the San Joaquin area and is based on the analyses listed in Table E-1.

#### EXPLANATION OF HEADINGS AND SYMBOLS USED IN TABLE E-1

State Well Number--The well numbering system used in this report for the location of wells is explained on page C-6.

Region, Basin, and Area Designation--The region used in this report and shown on Plate E-1, "Ground Water Quality Basins and Areas, San Joaquin Valley," is a geographic area and is defined in Section 13040 of the Water Code as Central Valley region. A decimal system of the form 0-00.00 has been used for basin numbering. The number to the left of the dash refers to the geographic region. On the right of the dash the first two digits refer to a hydrographic unit, generally designated as a basin, valley, or area. These are followed by decimals which designate a subbasin, area, or subarea within the basin, valley, or area. An example is given below:

5-22.20 The number 5 indicates the Central Valley region.

The number 22 indicates the San Joaquin Valley.

The number 20 indicates the Lower Kings River area.

Agency supplying data--The numbers in this column are the code numbers for the agency that sampled the well.

The last three digits of the agency code are numbers that designate, within specified serial limits, the type of agency from which the data were obtained, as follows:

<u>Code</u>	<u>Type of Agency</u>
000 through 049	Federal
050 through 099	State
100 through 199	County
200 through 399	Municipal
400 through 699	District--Water, Irrigation, Conservation, etc.
700 through 999	Private

The cooperating agencies, and code numbers assigned to them, are listed in the following tabulation:

<u>Agency Code</u>	<u>Agency</u>
5000	U. S. Geological Survey
5050	Department of Water Resources
5122	Stanislaus County Farm Advisor
5123	Tulare County Farm Advisor
5124	Kern County Farm Advisor
5126	Kings County Farm Advisor
5524	Turlock Irrigation District
5525	Merced Irrigation District
5631	Fresno Irrigation District
5640	Buena Vista Water Storage District
5641	Central California Irrigation District

— LINES OF EQUAL ELEVATION  
OF WATER IN WELLS  
SAN JOAQUIN VALLEY  
SPRING 1963  
SCALE OF 1:50,000

## EXPLANATION

## UNCONTINUED WATER-TABLE CONTOUR

Line of equal elevation of water in unconfined aquifers, marked with short dashes, contour interval 10 and 50 feet

## PRESSURE SURFACE CONTOUR

Line of equal elevation of Pressure Surface in aquifers that are confined or semi-confined, contours are marked with short dashes, contour interval 25 feet

## BARRIER

Ground water barrier

NOTE: Ground water contours in the San Joaquin Valley are based on data from the U.S.D.C. Water Resources Survey, made during December 1962. Other data used included data from the Water Survey of California, August 1963.
